EXPERIMENT 14

Pro-Code Extension Using Zoho Catalyst

Insurance Claim Status Check – Zoho Catalyst

1. Aim

To explore Zoho Catalyst development tools by viewing a serverless function and the Slate application deployment interface, and to understand how code-based extensions can be developed and deployed using Catalyst.

2. Procedure

1. Sign in to the Zoho Catalyst Console and open the required project, shown as Project-Rainfall.

2. Open the Serverless service from the left-side service menu and select the Functions section.

3. Open the function named claimStatusCheck and review its Overview page.

4. Observe the function details, including its name, runtime stack (Node 24), creation time, function ID, type, and creator.

5. Locate the Invocation URL displayed on the Overview page. This URL is used to invoke the serverless function from an application or API client.

6. Review the Daily Stats section, which displays total invocations, invocation errors, average invocation time, and time-outs. In the supplied screenshot, the invocation count, errors, and time-outs are zero, while average invocation time is shown as NA.

7. Navigate to the Slate service from the left-side service menu to open the application deployment interface.

8. Examine the available deployment methods, including importing a project from GitHub, GitLab, or Bitbucket, uploading a build ZIP file, and entering a repository URL.

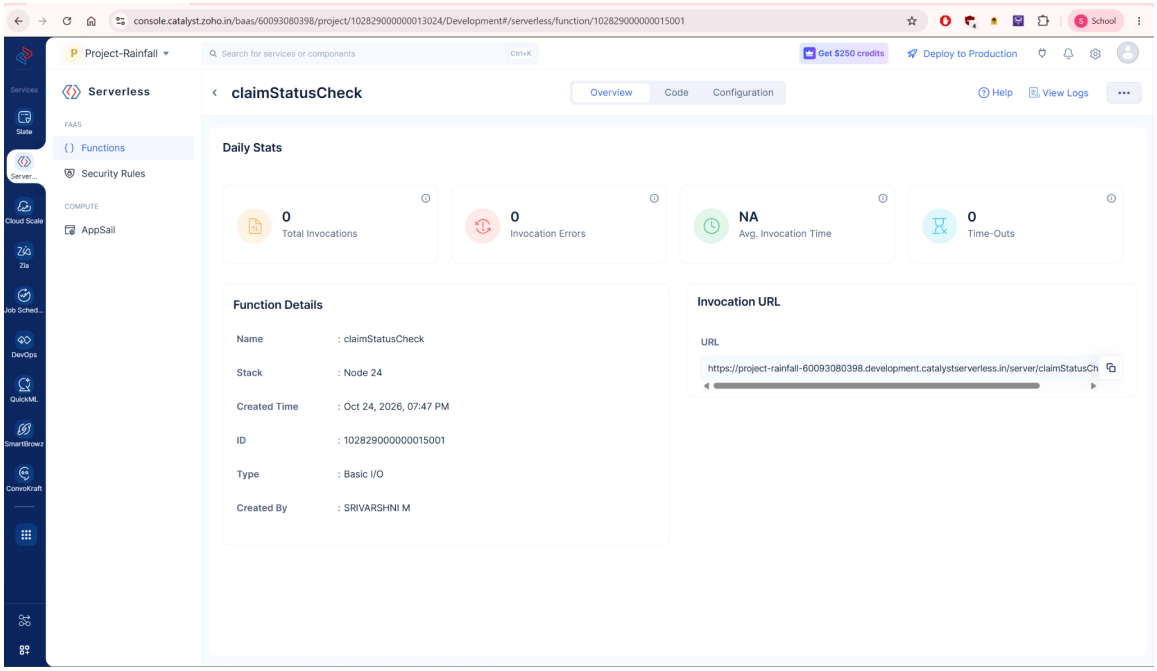

9. Review the starter templates provided for building applications, such as the Slyte starter template and the React Vite starter template.

10. Understand that a code-based extension can be developed using a supported framework, connected to a repository or uploaded as a build, and deployed through the Catalyst development environment.

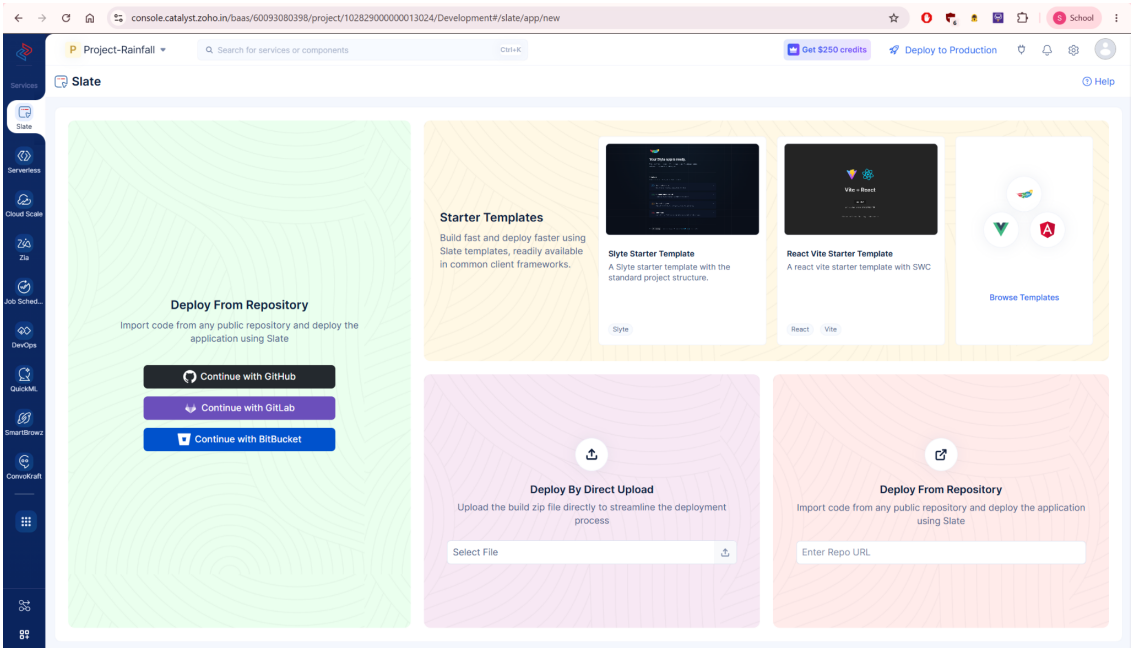

11. Capture screenshots of the serverless function overview and the Slate deployment page as evidence of the Catalyst development workflow.

3. Screenshots

Screenshot 1 – Zoho Catalyst Serverless Function overview for claimStatusCheck, showing function details, daily statistics, and Invocation URL.

Screenshot 2 – Zoho Catalyst Slate interface showing options for repository deployment, direct ZIP upload, and starter templates.

4. Result

The Zoho Catalyst Console was explored. The claimStatusCheck serverless function and its invocation details were reviewed, and the Slate interface was examined to understand the available methods for deploying code-based applications. The screenshots document the function overview and application deployment options.

Note: The supplied screenshots show the function overview and deployment interface. They do not show a completed function invocation or a successful application deployment, so those actions are not claimed as completed.
